# PHP

### Content

#### **PHP Basics:**

- Introduction to PHP
  - a PHP file, PHP workings, running PHP.
- Basic PHP syntax
  - variables, operators, if...else...and switch, while, do while, and for.
- Some useful PHP functions
- How to work with
  - HTML forms, cookies, files, time and date.
- How to create a basic checker for user-entered data

### Introduction to PHP

### Server-side programming tries to avoid the drawbacks

- Code is embedded in HTML pages, and evaluated on the server while the pages are being served. Add dynamically generated content to an existing HTML page.
  - Active Server Pages (ASP, Microsoft): The ASP engine is integrated into the web server so it does not require an additional process. It allows programmers to mix code within HTML pages instead of writing separate programs. (Drawback(?) Must be run on a server using Microsoft server software.)
  - Java Servlets (Sun): As CGI scripts, they are code that creates documents. These must be compiled
    as classes which are dynamically loaded by the web server when they are run.
  - Java Server Pages (JSP): Like ASP, another technology that allows developers to embed Java in web pages.

### Introduction to PHP

- Developed in 1995 by Rasmus Lerdorf (member of the Apache Group)
  - originally designed as a tool for tracking visitors at Lerdorf's Web site
  - within 2 years, widely used in conjunction with the Apache server
  - free, open-source
  - now fully integrated to work with mySQL databases
- PHP is similar to JavaScript, only it's a server-side language
  - PHP code is embedded in HTML using tags
  - when a page request arrives, the server recognizes PHP content via the file extension (.php or .phtml)
  - the server executes the PHP code, substitutes output into the HTML page
  - the resulting page is then downloaded to the client
  - user never sees the PHP code, only the output in the page
- The acronym PHP means (in a slightly recursive definition)
  - PHP: Hypertext Preprocessor

```
<ht.ml>
<!-- hello.php CS443 -->
<head><title>Hello World</title></head>
<body>
 This is going to be ignored by the PHP interpreter.
   <?php echo '<p>While this is going to be parsed.';
  This will also be ignored by the PHP preprocessor.
   <?php print('<p>Hello and welcome to <i>my</i>
page!');
    ?>
  <?php
   //This is a comment
  /*
   This is
  a comment
  block
  ?>
</body>
</html>
```

A PHP scripting block always starts with <?php and ends with ?>. A PHP scripting block can be placed (almost) anywhere in an HTML document.

```
for output

a semicolon (;)
at the end of each
statement

// for a single-line comment
/* and */ for a large
```

comment block.

print and echo

view the output page

VIỆN CÔNG NGHỆ THÔNG TIN VÀ TRUYỀN THÔNG

The server executes the print and echo statements, substitutes output.

#### **Scalars**

```
<html><head></head>
<!-- scalars.php CS443 -->
<body> 
<?php
$foo = true; if ($foo) echo "It is TRUE! <br /> \n";
$txt='1234'; echo "$txt <br /> \n";
a = 1234; echo "$a <br/> \n";
a = -123;
echo "$a <br /> \n";
a = 1.234;
echo "$a <br /> \n";
a = 1.2e3;
echo "$a <br /> \n";
$a = 7E-10;
echo "$a <br /> \n";
echo 'Arnold once said: "I\'ll be back"', "<br /> \n";
$beer = 'Heineken';
echo "$beer's taste is great <br /> \n";
str = << EOD
Example of string
spanning multiple lines
using "heredoc" syntax.
EOD;
echo $str;
?>
</body>
</html>
```

view the output page

All variables in PHP start with a \$ sign symbol. A variable's type is determined by the context in which that variable is used (i.e. there is no strong-typing in PHP).

```
Four scalar types:

boolean

true or false
integer,
float,
floating point numbers
string
single quoted
double quoted
```

### Arrays

```
<?php
$arr = array("foo" => "bar", 12 => true);
echo $arr["foo"]; // bar
echo $arr[12]; // 1
?>
```

```
<?php
array(5 => 43, 32, 56, "b" => 12);
array(5 => 43, 6 => 32, 7 => 56, "b" => 12);
?>
```

```
array() = creates arrays

key = either an integer or a string.

value = any PHP type.
```

if no key given (as in example), the PHP interpreter uses (maximum of the integer indices + 1).

if an existing key, its value will be overwritten.

#### can set values in an array

unset () removes a key/value pair

makes reindexing effect (indexing numerically)

\*Find more on arrays

### Constants

A constant is an identifier (name) for a simple value. A constant is case-sensitive by default. By convention, constant identifiers are always uppercase.

```
<?php
// Valid constant names
define("FOO", "something");
define("FOO2", "something else");
define("FOO BAR", "something more");
// Invalid constant names (they shouldn't start
// with a number!)
define("2FOO", "something");
// This is valid, but should be avoided:
// PHP may one day provide a "magical" constant
// that will break your script
define(" FOO ", "something");
?>
```

You can access constants anywhere in your script without regard to scope.

## Operators

- Arithmetic Operators: +, -, \*,/ , %, ++, --
- Assignment Operators: =, +=, -=, \*=, /=, %=

Example	Is the same as	
x+=	$x=x+\lambda$	
х-=У	x=x-y	
x*=y	x=x*y	
x/=y	x=x/y	
x%=À	x=x%A	

- Comparison Operators: ==, !=, >, <, >=, <=
- Logical Operators: &&, ||, !
- String Operators: . and .= (for string concatenation)

```
$a = "Hello ";
$b = $a . "World!"; // now $b contains "Hello World!"

$a = "Hello ";
$a .= "World!";
```

### Conditionals: if else

#### Can execute a set of code depending on a condition

```
<html><head></head>
<!-- if-cond.php CS443 -->
<body>
<?php
$d=date("D");
echo $d, "<br/>";
if ($d=="Fri")
     echo "Have a nice weekend! <br/>";
else
     echo "Have a nice day! <br/>";
x=10;
if ($x==10)
     echo "Hello<br />";
     echo "Good morning<br />";
?>
</body>
</html>
                           view the output page
```

```
if (condition)
code to be executed if condition
is true;
else
code to be executed if condition
is false;
```

date() is a built-in PHP function that can be called with many different parameters to return the date (and/or local time) in various formats

In this case we get a three letter string for the day of the week.

### Conditionals: switch

```
<html><head></head>
<body>
<!-- switch-cond.php CS443 -->
<?php
x = rand(1,5); // random integer
echo "x = x < br/> /r/;
switch ($x)
case 1:
 echo "Number 1";
 break:
case 2:
 echo "Number 2";
 break;
case 3:
  echo "Number 3";
 break;
default:
 echo "No number between 1 and 3";
 break;
</body>
                      view the output page
</ht.ml>
```

#### Can select one of many sets of lines to execute

```
switch (expression)
{
  case label1:
    code to be executed if expression = label1;
    break;
  case label2:
    code to be executed if expression = label2;
    break;
  default:
    code to be executed
    if expression is different
    from both label1 and label2;
    break;
}
```

### Looping: while and do-while

### Can loop depending on a condition

```
<html><head></head>
<body>
<!php
$i=1;
while($i <= 5)
{
   echo "The number is $i <br />";
   $i++;
}
?>
</body>
</html>
   view the output page
```

loops through a block of code if, and as long as, a specified condition is true

```
<html><head></head>
<body>
<!php
$i=0;
do
{
    $i++;
    echo "The number is $i <br />";
}
while($i <= 10);
?>
</body>
</html>
    view the output page
```

loops through a block of code once, and then repeats the loop as long as a special condition is true (so will always execute at least once)

# Looping: for and foreach

#### Can loop depending on a "counter"

```
<?php
for ($i=1; $i<=5; $i++)
{
echo "Hello World!<br />";
}
?>
```

loops through a block of code a specified number of times

view the output page

```
<?php
$a_array = array(1, 2, 3, 4);
foreach ($a_array as $value)
{
    $value = $value * 2;
    echo "$value <br/> \n";
}
?>
```

```
<?php
$a_array=array("a","b","c");
foreach ($a_array as $key => $value)
{
   echo $key . " = " . $value . "\n";
}
?>
```

loops through a block of code for each element in an array

### **User Defined Functions**

#### Can define a function using syntax such as the following:

```
<?php
function foo($arg_1, $arg_2, /* ..., */ $arg_n)
{
   echo "Example function.\n";
   return $retval;
}
?>
```

Can also define conditional functions, functions within functions, and recursive functions.

#### Can return a value of any type

```
<?php
function square($num)
{
   return $num * $num;
}
echo square(4);
?>
```

```
<?php
function small_numbers()
{
   return array (0, 1, 2);
}
list ($zero, $one, $two) = small_numbers();
echo $zero, $one, $two;
?>
```

```
<?php
function takes_array($input)
{
   echo "$input[0] + $input[1] = ", $input[0]+$input[1];
}
   takes_array(array(1,2));
?>
```

view the output page

### Variable Scope

The scope of a variable is the context within which it is defined.

```
<?php
$a = 1; /* limited variable scope */
function Test()
{
   echo $a;
   /* reference to local scope variable */
}
Test();
?>
```

The scope is local within functions, and hence the value of \$a is undefined in the "echo" statement.

```
<?php
$a = 1;
$b = 2;
function Sum()
{
    global $a, $b;
    $b = $a + $b;
}
Sum();
echo $b;
?>
```

global refers to its global

version.

view the output page

```
<?php
function Test()
{
    static $a = 0;
    echo $a;
    $a++;
}
Test1();
Test1();
Test1();
?>
```

static

does not lose its value.

### Including Files

#### The include() statement includes and evaluates the specified file.

```
vars.php
<?php
$color = 'green';
$fruit = 'apple';
?>
// test.php
<?php
echo "A $color $fruit"; // A
include 'vars.php';
echo "A $color $fruit"; // A green apple
?>
                   view the output page
```

```
<?php
function foo()
  global $color;
  include ('vars.php');
  echo "A $color $fruit";
/* vars.php is in the scope of foo() so
  $fruit is NOT available outside of this *
 * scope. $color is because we declared it *
* as global.
foo();
                         // A green apple
echo "A $color $fruit"; // A green
?>
                          view the output page
```

\*The scope of variables in "included" files depends on where the "include" file is added!

You can use the include\_once, require, and require\_once statements in similar ways.

### PHP Information

The phpinfo() function is used to output PHP information about the version installed on the server, parameters selected when installed, etc.

```
<html><head></head>
<!- info.php CS443
<body>
<?php
// Show all PHP information
phpinfo();
?>
<?php
// Show only the general information
phpinfo(INFO_GENERAL);
?>
</body>
</html>
```

view the output page

INFO\_GENERAL The configuration line,

php.ini location,

build date, Web Server,

System and more

INFO CREDITS PHP 4 credits

INFO\_CONFIGURATION Local and master values

for php directives

INFO\_MODULES Loaded modules

INFO ENVIRONMENT Environment variable

information

INFO\_VARIABLES All predefined variables

from EGPCS

INFO\_LICENSE PHP license information

INFO\_ALL Shows all of the above (default)

### Server Variables

The \$ SERVER array variable is a reserved variable that contains all server information.

```
<html><head></head>
<body>
<?php
echo "Referer: " . $ SERVER["HTTP REFERER"] . "<br />";
echo "Browser: " . $ SERVER["HTTP USER AGENT"] . "<br/>';
echo "User's IP address: " . $ SERVER["REMOTE ADDR"];
?>
<?php
echo "<br/><br/>";
echo "<h2>All information</h2>";
foreach ($ SERVER as $key => $value)
    echo key . " = " . value . " < br/>";
?>
</body>
</html>
                                         view the output page
```

\$\_SERVER info on php.net

The \$\_SERVER is a super global variable, i.e. it's available in all scopes of a PHP script.

VIỆN CÔNG NGHỆ THÔNG TIN VÀ TRUYỀN THÔNG

### File Open

The fopen ("file\_name", "mode") function is used to open files in PHP.

```
r Read only. r+ Read/Write.
w Write only. w+ Read/Write.
a Append. a+ Read/Append.
x Create and open for write only. x+ Create and open for read/write.
```

```
<?php
$fh=fopen("welcome.txt","r");
?>
```

For w, and a, if no file exists, it tries to create it (use with caution, i.e. check that this is the case, otherwise you'll overwrite an existing file).

```
<?php
if
( !($fh=fopen("welcome.txt","r")) )
exit("Unable to open file!");
?>
```

For x if a file exists, this function fails (and returns 0).

If the fopen () function is unable to open the specified file, it returns 0 (false).

### File Workings

```
<?php
$myFile = "welcome.txt";
if (!($fh=fopen($myFile,'r')))
exit("Unable to open file.");
while (!feof($fh))
{
$x=fgetc($fh);
echo $x;
}
fclose($fh);
?>
    view the output page
```

```
<?php
$lines = file('welcome.txt');
foreach ($lines as $l_num => $line)
{
  echo "Line #{$l_num}:"
  .$line."<br/>";
}
?>
  view the output page
```

```
<?php
$myFile = "welcome.txt";
$fh = fopen($myFile, 'r');
$theData = fgets($fh);
fclose($fh);
echo $theData;
?>
view the output page
```

```
<?php
$myFile = "testFile.txt";
$fh = fopen($myFile, 'a') or
die("can't open file");
$stringData = "New Stuff 1\n";
fwrite($fh, $stringData);
$stringData = "New Stuff 2\n";
fwrite($fh, $stringData);
fclose($fh);
?>
view the output page
```

```
fclose() closes a file.
fgetc() reads a single character
fwrite(), fputs ()
writes a string with and without \n
```

feof ( ) determines if the end is true.

fgets() reads a line of data
file() reads entire file into an
array

### Form Handling

Any form element is automatically available via one of the built-in PHP variables (provided that HTML element has a "name" defined with it).

```
<html>
<!-- welcome.php COMP 519 -->
<body>

Welcome <?php echo $_POST["name"]."."; ?><br />
You are <?php echo $_POST["age"]; ?> years old!

</body>
</html>
```

```
$_POST contains all POST data.
```

\$\_GET contains all GET data.

view the output page

### Cookie Workings

setcookie (name, value, expire, path, domain) creates cookies.

```
<?php
setcookie("uname", $_POST["name"], time()+36000);
?>
<html>
<body>

Dear <?php echo $_POST["name"] ?>, a cookie was set on this page! The cookie will be active when the client has sent the cookie back to the server.

</body>
</html>
view the output page
```

```
any output) as it's part of the header information sent with the page.
```

setcookie() must appear

BEFORE <html> (or

NOTE:

\$\_COOKIE
contains all COOKIE data.

isset()

finds out if a cookie is set

use the cookie name as a variable

### Getting Time and Date

date() and time () formats a time or a date.

```
<?php
//Prints something like: Monday
echo date("1");

//Like: Monday 15th of January 2003 05:51:38 AM
echo date("1 jS \of F Y h:i:s A");

//Like: Monday the 15th
echo date("1 \\t\h\e jS");
?>
    view the output page
```

date() returns a string formatted according to the specified format.

time() returns current Unix timestamp

view the output page

### Required Fields in User-Entered Data

A multipurpose script which asks users for some basic contact information and then checks to see that the required fields have been entered.

```
<html>
<!-- form_checker.php CS443 -->
<head>
<title>PHP Form example</title>
</head>
<body>
<?php
/*declare some functions*/
```

#### **Print Function**

```
function print_form($f_name, $l_name, $email, $os)
{
?>
    <form action="form_checker.php" method="post">
        First Name: <input type="text" name="f_name" value="<?php echo $f_name?>" /> <br/>
        Last Name <b>*</b>:<input type="text" name="l_name" value="<?php echo $l_name?>" /> <br/>
        Email Address <b>*</b>:<input type="text" name="email" value="<?php echo $email?>" /> <br/>
        Operating System: <input type="text" name="os" value="<?php echo $os?>" /> <br/>
        <input type="submit" name="submit" value="Submit" /> <input type="reset" />
        </form>

        //** end of "print_form" function
```

### **Check and Confirm Functions**

```
function check_form($f_name, $l_name, $email, $os)
{
  if (!$l_name||!$email) {
    echo "<h3>You are missing some required fields!</h3>";
    print_form($f_name, $l_name, $email, $os);
  }
  else{
    confirm_form($f_name, $l_name, $email, $os);
  }
} //** end of "check_form" function
```

# Main Program

```
/*Main Program*/
if (!$ POST["submit"])
?>
<h3>Please enter your information</h3>
Fields with a "<b>*</b>" are required.
<?php
print_form("","","","");
else{
check_form($_POST["f_name"],$_POST["l_name"],$_POST["email"],$_POST["os"]);
?>
</body>
</html>
                                                          view the output page
```

# Learning Outcomes

#### In the lecture you have learned

- What is PHP and what are some of its workings.
- Basic PHP syntax
  - variables, operators, if...else...and switch, while, do while, and for.
- Some useful PHP functions
- How to work with
  - HTML forms, cookies, files, time and date.
- How to create a basic checker for user-entered data.
